12. CHEMICAL FACT SHEETS

In experimental animals, prolonged exposure in the diet causes liver damage. Chlordane produces liver tumours in mice, but the weight of evidence indicates that it is not genotoxic. Chlordane can interfere with cell communication in vitro, a characteristic of many tumour promoters. IARC re-evaluated chlordane in 1991 and concluded that there is inadequate evidence for its carcinogenicity in humans and sufficient evidence for its carcinogenicity in animals, classifying it in Group 2B.

Chloride

Chloride in drinking-water originates from natural sources, sewage and industrial effluents, urban runoff containing de-icing salt and saline intrusion.

The main source of human exposure to chloride is the addition of salt to food, and the intake from this source is usually greatly in excess of that from drinking-water.

| Reason for not establishing a guideline value | Not of health concern at levels found in drinking-water |
|---|---|
| Additional comments | May affect acceptability of drinking-water |
| Assessment date | 1993 |
| Principal reference | WHO (2003) Chloride in drinking-water |

Excessive chloride concentrations increase rates of corrosion of metals in the distribution system, depending on the alkalinity of the water. This can lead to increased concentrations of metals in the supply.

No health-based guideline value is proposed for chloride in drinking-water. However, chloride concentrations in excess of about 250 mg/l can give rise to detectable taste in water (see chapter 10).

Chlorine

Chlorine is produced in large amounts and widely used both industrially and domestically as an important disinfectant and bleach. In particular, it is widely used in the disinfection of swimming pools and is the most commonly used disinfectant and oxidant in drinking-water treatment. In water, chlorine reacts to form hypochlorous acid and hypochlorites. Concentrations of chlorate and some perchlorates increase in hypochlorite solutions upon storage at high ambient temperatures or when new hypochlorite is added to old hypochlorite.

| Guideline value | 5 mg/l (5000 μg/l) for free chlorine |
|--------------------|--|
| Occurrence | Present in most disinfected drinking-water at concentrations of 0.2–1 mg/l |
| TDI | 150 μg/kg body weight, derived from a NOAEL for the absence of toxicity in rodents ingesting chlorine in drinking-water for 2 years |
| Limit of detection | 0.01 μg/l following pre-column derivatization to 4-bromoacetanilide by HPLC; 10 μg/l as free chlorine by colorimetry; 200 μg/l by ion chromatography |
